#### CPU Instruction Set Details

A

This appendix provides a detailed description of the operation of each R4000 instruction in both 32- and 64-bit modes. The instructions are listed in alphabetical order.

Exceptions that may occur due to the execution of each instruction are listed after the description of each instruction. Descriptions of the immediate cause and manner of handling exceptions are omitted from the instruction descriptions in this appendix.

Figures at the end of this appendix list the bit encoding for the constant fields of each instruction, and the bit encoding for each individual instruction is included with that instruction.

#### **A.1 Instruction Classes**

CPU instructions are divided into the following classes:

- **Load** and **Store** instructions move data between memory and general registers. They are all I-type instructions, since the only addressing mode supported is *base register* + 16-bit immediate offset.
- **Computational** instructions perform arithmetic, logical and shift operations on values in registers. They occur in both R-type (both operands are registers) and I-type (one operand is a 16-bit immediate) formats.
- **Jump** and **Branch** instructions change the control flow of a program. Jumps are always made to absolute 26-bit word addresses (J-type format), or register addresses (R-type), for returns and dispatches. Branches have 16-bit offsets relative to the program counter (I-type). **Jump and Link** instructions save their return address in register 31.
- Coprocessor instructions perform operations in the coprocessors. Coprocessor loads and stores are I-type.
   Coprocessor computational instructions have coprocessordependent formats (see the FPU instructions in Appendix B).
   Coprocessor zero (CP0) instructions manipulate the memory management and exception handling facilities of the processor.
- **Special** instructions perform a variety of tasks, including movement of data between special and general registers, trap, and breakpoint. They are always R-type.

#### **A.2 Instruction Formats**

Every CPU instruction consists of a single word (32 bits) aligned on a word boundary and the major instruction formats are shown in Figure A-1.

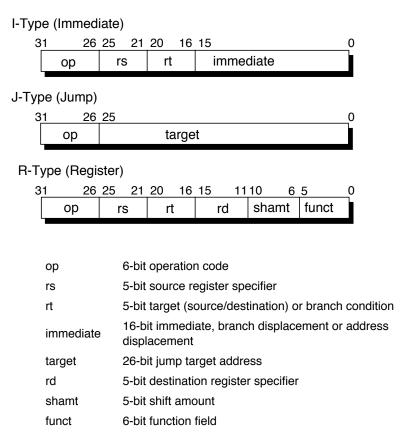

Figure A-1 CPU Instruction Formats

#### **A.3 Instruction Notation Conventions**

In this appendix, all variable subfields in an instruction format (such as *rs*, *rt*, *immediate*, etc.) are shown in lowercase names.

For the sake of clarity, we sometimes use an alias for a variable subfield in the formats of specific instructions. For example, we use rs = base in the format for load and store instructions. Such an alias is always lower case, since it refers to a variable subfield.

Figures with the actual bit encoding for all the mnemonics are located at the end of this Appendix, and the bit encoding also accompanies each instruction.

In the instruction descriptions that follow, the *Operation* section describes the operation performed by each instruction using a high-level language notation. The R4000 can operate as either a 32- or 64-bit microprocessor and the operation for both modes is included with the instruction description.

Special symbols used in the notation are described in Table A-1.

Table A-1 CPU Instruction Operation Notations

Symbol	Meaning				
<b>←</b>	Assignment.				
II	Bit string concatenation.				
xy	Replication of bit value $x$ into a $y$ -bit string. Note: $x$ is always a single-bit value.				
x <sub>y:z</sub>	Selection of bits $y$ through $z$ of bit string $x$ . Little-endian bit notation is always used. If $y$ is less than $z$ , this expression is an empty (zero length) bit string.				
+	2's complement or floating-point addition.				
-	2's complement or floating-point subtraction.				
*	2's complement or floating-point multiplication.				
div	2's complement integer division.				
mod	2's complement modulo.				
/	Floating-point division.				
<	2's complement less than comparison.				
and	Bit-wise logical AND.				
or	Bit-wise logical OR.				
xor	Bit-wise logical XOR.				
nor	Bit-wise logical NOR.				
GPR[x]	General-Register x. The content of GPR[0] is always zero. Attempts to alter the content of GPR[0] have no effect.				
CPR[z,x]	Coprocessor unit z, general register x.				
CCR[z,x]	Coprocessor unit z, control register x.				
COC[z]	Coprocessor unit z condition signal.				
BigEndianMem	Big-endian mode as configured at reset (0 $\rightarrow$ Little, 1 $\rightarrow$ Big). Specifies the endianness of the memory interface (see LoadMemory and StoreMemory), and the endianness of Kernel and Supervisor mode execution.				
ReverseEndian	Signal to reverse the endianness of load and store instructions. This feature is available in User mode only, and is effected by setting the $RE$ bit of the $Status$ register. Thus, ReverseEndian may be computed as ( $SR_{25}$ and User mode).				
BigEndianCPU	The endianness for load and store instructions (0 $\rightarrow$ Little, 1 $\rightarrow$ Big). In User mode, this endianness may be reversed by setting SR <sub>25</sub> . Thus, BigEndianCPU may be computed as BigEndianMem XOR ReverseEndian.				
LLbit	Bit of state to specify synchronization instructions. Set by <i>LL</i> , cleared by <i>ERET</i> and <i>Invalidate</i> and read by <i>SC</i> .				
T+i:	Indicates the time steps between operations. Each of the statements within a time step are defined to be executed in sequential order (as modified by conditional and loop constructs). Operations which are marked $T+i$ : are executed at instruction cycle $i$ relative to the start of execution of the instruction. Thus, an instruction which starts at time $j$ executes operations marked $T+i$ : at time $i+j$ . The interpretation of the order of execution between two instructions or two operations which execute at the same time should be pessimistic; the order is not defined.				

#### **Instruction Notation Examples**

The following examples illustrate the application of some of the instruction notation conventions:

#### Example #1:

GPR[rt] ← immediate II 0<sup>16</sup>

Sixteen zero bits are concatenated with an immediate value (typically 16 bits), and the 32-bit string (with the lower 16 bits set to zero) is assigned to General-Purpose Register *rt*.

#### Example #2:

 $(immediate_{15})^{16}$  II  $immediate_{15...0}$ 

Bit 15 (the sign bit) of an immediate value is extended for 16 bit positions, and the result is concatenated with bits 15 through 0 of the immediate value to form a 32-bit sign extended value.

#### A.4 Load and Store Instructions

In the R4000 implementation, the instruction immediately following a load may use the loaded contents of the register. In such cases, the hardware *interlocks*, requiring additional real cycles, so scheduling load delay slots is still desirable, although not required for functional code.

Two special instructions are provided in the R4000 implementation of the MIPS ISA, Load Linked and Store Conditional. These instructions are used in carefully coded sequences to provide one of several synchronization primitives, including test-and-set, bit-level locks, semaphores, and sequencers/event counts.

In the load and store descriptions, the functions listed in Table A-2 are used to summarize the handling of virtual addresses and physical memory.

Table A-2 Load and Store Common Functions

Function	Meaning
AddressTranslation	Uses the TLB to find the physical address given the virtual address. The function fails and an exception is taken if the required translation is not present in the TLB.
LoadMemory	Uses the cache and main memory to find the contents of the word containing the specified physical address. The low-order two bits of the address and the <i>Access Type</i> field indicates which of each of the four bytes within the data word need to be returned. If the cache is enabled for this access, the entire word is returned and loaded into the cache.
StoreMemory	Uses the cache, write buffer, and main memory to store the word or part of word specified as data in the word containing the specified physical address. The low-order two bits of the address and the <i>Access Type</i> field indicates which of each of the four bytes within the data word should be stored.

As shown in Table A-3, the *Access Type* field indicates the size of the data item to be loaded or stored. Regardless of access type or byte-numbering order (endianness), the address specifies the byte which has the smallest byte address in the addressed field. For a big-endian machine, this is the leftmost byte and contains the sign for a 2's complement number; for a little-endian machine, this is the rightmost byte.

Table A-3 Access Type Specifications for Loads/Stores

Access Type Mnemonic	Value	Meaning
DOUBLEWORD	7	8 bytes (64 bits)
SEPTIBYTE	6	7 bytes (56 bits)
SEXTIBYTE	5	6 bytes (48 bits)
QUINTIBYTE	4	5 bytes (40 bits)
WORD	3	4 bytes (32 bits)
TRIPLEBYTE	2	3 bytes (24 bits)
HALFWORD	1	2 bytes (16 bits)
BYTE	0	1 byte (8 bits)

The bytes within the addressed doubleword which are used can be determined directly from the access type and the three low-order bits of the address.

#### A.5 Jump and Branch Instructions

All jump and branch instructions have an architectural delay of exactly one instruction. That is, the instruction immediately following a jump or branch (that is, occupying the delay slot) is always executed while the target instruction is being fetched from storage. A delay slot may not itself be occupied by a jump or branch instruction; however, this error is not detected and the results of such an operation are undefined.

If an exception or interrupt prevents the completion of a legal instruction during a delay slot, the hardware sets the *EPC* register to point at the jump or branch instruction that precedes it. When the code is restarted, both the jump or branch instructions and the instruction in the delay slot are reexecuted.

Because jump and branch instructions may be restarted after exceptions or interrupts, they must be restartable. Therefore, when a jump or branch instruction stores a return link value, register *31* (the register in which the link is stored) may not be used as a source register.

Since instructions must be word-aligned, a **Jump Register** or **Jump and Link Register** instruction must use a register whose two low-order bits are zero. If these low-order bits are not zero, an address exception will occur when the jump target instruction is subsequently fetched.

#### **A.6 Coprocessor Instructions**

Coprocessors are alternate execution units, which have register files separate from the CPU. The MIPS architecture provides four coprocessor units, or classes, and these coprocessors have two register spaces, each space containing thirty-two 32-bit registers.

- The first space, coprocessor general registers, may be directly loaded from memory and stored into memory, and their contents may be transferred between the coprocessor and processor.
- The second space, coprocessor control registers, may only have their contents transferred directly between the coprocessor and the processor. Coprocessor instructions may alter registers in either space.

#### A.7 System Control Coprocessor (CP0) Instructions

There are some special limitations imposed on operations involving CP0 that is incorporated within the CPU. Although load and store instructions to transfer data to/from coprocessors and to move control to/from coprocessor instructions are generally permitted by the MIPS architecture, CP0 is given a somewhat protected status since it has responsibility for exception handling and memory management. Therefore, the move to/from coprocessor instructions are the only valid mechanism for writing to and reading from the CP0 registers.

Several CP0 instructions are defined to directly read, write, and probe TLB entries and to modify the operating modes in preparation for returning to User mode or interrupt-enabled states.

ADD Add ADD

31 26	25 21	20 16	15 11	1 10 6	5 0
SPECIAL	rs	rt	rd	0	ADD
000000			10	00000	100000
6	5	5	5	5	6

#### **Format:**

ADD rd, rs, rt

#### **Description:**

The contents of general register rs and the contents of general register rt are added to form the result. The result is placed into general register rd. In 64-bit mode, the operands must be valid sign-extended, 32-bit values.

An overflow exception occurs if the carries out of bits 30 and 31 differ (2's complement overflow). The destination register rd is not modified when an integer overflow exception occurs.

#### Operation:

32 T: 
$$GPR[rd] \leftarrow GPR[rs] + GPR[rt]$$
64 T:  $temp \leftarrow GPR[rs] + GPR[rt]$ 

$$GPR[rd] \leftarrow (temp_{31})^{32} \parallel temp_{31...0}$$

#### **Exceptions:**

Integer overflow exception

### **ADDI**

#### **Add Immediate**

### **ADDI**

31 26	25 21	20 16	15	0
ADDI 0 0 1 0 0 0	rs	rt	immediate	
6	5	5	16	_

#### Format:

ADDI rt, rs, immediate

#### **Description:**

The 16-bit *immediate* is sign-extended and added to the contents of general register *rs* to form the result. The result is placed into general register *rt*. In 64-bit mode, the operand must be valid sign-extended, 32-bit values.

An overflow exception occurs if carries out of bits 30 and 31 differ (2's complement overflow). The destination register rt is not modified when an integer overflow exception occurs.

#### **Operation:**

32 T: GPR [rt] 
$$\leftarrow$$
 GPR[rs] +(immediate<sub>15</sub>)<sup>16</sup> | | immediate<sub>15...0</sub>

64 T: temp  $\leftarrow$  GPR[rs] + (immediate<sub>15</sub>)<sup>48</sup> | | immediate<sub>15...0</sub>

GPR[rt]  $\leftarrow$  (temp<sub>31</sub>)<sup>32</sup> || temp<sub>31...0</sub>

#### **Exceptions:**

Integer overflow exception

### **ADDIU**

#### **Add Immediate Unsigned**

### **ADDIU**

31 26	25 21	20 16	15	0
ADDIU 0 0 1 0 0 1	rs	rt	immediate	
6	5	5	16	_

#### **Format:**

ADDIU rt, rs, immediate

#### **Description:**

The 16-bit *immediate* is sign-extended and added to the contents of general register *rs* to form the result. The result is placed into general register *rt*. No integer overflow exception occurs under any circumstances. In 64-bit mode, the operand must be valid sign-extended, 32-bit values.

The only difference between this instruction and the ADDI instruction is that ADDIU never causes an overflow exception.

#### Operation:

32 T: GPR [rt] 
$$\leftarrow$$
 GPR[rs] + (immediate<sub>15</sub>)<sup>16</sup> II immediate<sub>15...0</sub>

64 T: 
$$temp \leftarrow GPR[rs] + (immediate_{15})^{48} \mid \mid immediate_{15...0}$$
  
 $GPR[rt] \leftarrow (temp_{31})^{32} \mid l \mid temp_{31...0}$ 

#### **Exceptions:**

### **ADDU**

#### **Add Unsigned**

### **ADDU**

31 26	25 21	20 16	15 11	10 6	5 0

#### Cache

### **CACHE**

31 26	25 21	20 16	15 0
CACHE 1 0 1 1 1 1	base	ор	offset
6	5	5	16

#### **Format:**

CACHE op, offset(base)

#### **Description:**

The 16-bit *offset* is sign-extended and added to the contents of general register *base* to form a virtual address. The virtual address is translated to a physical address using the TLB, and the 5-bit sub-opcode specifies a cache operation for that address.

If CP0 is not usable (User or Supervisor mode) the CP0 enable bit in the *Status* register is clear, and a coprocessor unusable exception is taken. The operation of this instruction on any operation/cache combination not listed below, or on a secondary cache when none is present, is undefined. The operation of this instruction on uncached addresses is also undefined.

The Index operation uses part of the virtual address to specify a cache block.

For a primary cache of  $2^{\text{CACHEBITS}}$  bytes with  $2^{\text{LINEBITS}}$  bytes per tag,  $v A d d r_{\text{CACHEBITS}} \dots LINEBITS$  specifies the block.

For a secondary cache of 2<sup>CACHEBITS</sup> bytes with 2<sup>LINEBITS</sup> bytes per tag, pAddr<sub>CACHEBITS</sub> ... LINEBITS specifies the block.

Index Load Tag also uses vAddr<sub>LINEBITS... 3</sub> to select the doubleword for reading ECC or parity. When the *CE* bit of the *Status* register is set, Hit WriteBack, Hit WriteBack Invalidate, Index WriteBack Invalidate, and Fill also use vAddr<sub>LINEBITS</sub> ...  $_3$  to select the doubleword that has its ECC or parity modified. This operation is performed unconditionally.

The Hit operation accesses the specified cache as normal data references, and performs the specified operation if the cache block contains valid data with the specified physical address (a hit). If the cache block is invalid or contains a different address (a miss), no operation is performed.

## Cache (continued)

## **CACHE**

Write back from a primary cache goes to the secondary cache (if there is one), otherwise to memory. Write back from a secondary cache always goes to memory. A secondary write back always writes the most recent data; the data comes from the primary data cache, if present, and modified (the *W* bit is set). Otherwise the data comes from the specified secondary cache. The address to be written is specified by the cache tag and not the translated physical address.

TLB Refill and TLB Invalid exceptions can occur on any operation. For Index operations (where the physical address is used to index the cache but need not match the cache tag) unmapped addresses may be used to avoid TLB exceptions. This operation never causes TLB Modified or Virtual Coherency exceptions.

Bits 17...16 of the instruction specify the cache as follows:

Code	Name	Cache	
0	I	primary instruction	
1	D	primary data	
2	SI	secondary instruction	
3	SD	secondary data (or combined instruction/data)	

## Cache (continued)

## **CACHE**

Bits 20...18 (this value is listed under the **Code** column) of the instruction specify the operation as follows:

Code	Caches	Name	Operation
0	I, SI	Index Invalidate	Set the cache state of the cache block to Invalid.
0	D	Index Writeback Invalidate	Examine the cache state and Writeback bit ( <i>W</i> bit) of the primary data cache block at the index specified by the virtual address. If the state is not Invalid and the <i>W</i> bit is set, write the block back to the secondary cache (if present) or to memory (if no secondary cache). The address to write is taken from the primary cache tag. When a secondary cache is present, and the <i>CE</i> bit of the <i>Status</i> register is set, the contents of the <i>ECC</i> register is XOR'd into the computed check bits during the write to the secondary cache for the addressed doubleword. Set the cache state of primary cache block to Invalid. The <i>W</i> bit is unchanged (and irrelevant because the state is Invalid).
0	SD	Index Writeback Invalidate	Examine the cache state of the secondary data cache block at the index specified by the physical address. If the block is dirty (the state is Dirty Exclusive or Dirty Shared), write the data back to memory. Like all secondary writebacks, the operation writes any modified data for the addresses from the primary data cache. The address to write is taken from the secondary cache tag. The <i>Pldx</i> field of the secondary tag is used to determine the locations in the primaries to check for matching primary blocks. In all cases, set the state of the secondary cache block and all matching primary subblocks to Invalid. No Invalidate is sent on the R4000's system interface.
1	All	Index Load Tag	Read the tag for the cache block at the specified index and place it iinto the <i>TagLo</i> and <i>TagHi</i> CP0 registers, ignoring any ECC or parity errors. Also load the data ECC or parity bits into the ECC register.
2	All	Index Store Tag	Write the tag for the cache block at the specified index from the <i>TagLo</i> and <i>TagHi</i> CP0 registers. The processor uses computed parity for the primary caches and the <i>TagLo</i> register in the case of the secondary cache.

## Cache (continued)

## **CACHE**

Code	Caches	Name	Operation
3	SD	Create Dirty Exclusive	This operation is used to avoid loading data needlessly from memory when writing new contents into an entire cache block. If the cache block is valid but does not contain the specified address (a valid miss) the secondary block is vacated. The data is written back to memory if dirty and all matching blocks in both primary caches are invalidated. As usual during a secondary writeback, if the primary data cache contains modified data (matching blocks with W bit set) that modified data is written to memory. If the cache block is valid and contains the specified physical address (a hit), the operation cleans up the primary caches to avoid virtual aliases: all blocks in both primary caches that match the secondary line are invalidated without writeback. Note that the search for matching primary blocks uses the virtual index of the Pldx field of the secondary cache tag (the virtual index when the location was last used) and not the virtual index of the virtual address used in the operation (the virtual index where the location will now be used). If the secondary tag and address do not match (miss), or the tag and address do match (hit) and the block is in a shared state, an invalidate for the specified address is sent over the System interface. In all cases, the cache block tag must be set to the specified physical address, the cache state must be set to Dirty Exclusive, and the virtual index field set from the virtual address. The CH bit in the Status register is set or cleared to indicate a hit or miss.
3	D	Create Dirty Exclusive	This operation is used to avoid loading data needlessly from secondary cache or memory when writing new contents into an entire cache block. If the cache block does not contain the specified address, and the block is dirty, write it back to the secondary cache (if present) or otherwise to memory. In all cases, set the cache block tag to the specified physical address, set the cache state to Dirty Exclusive.
4	I,D	Hit Invalidate	If the cache block contains the specified address, mark the cache block invalid.
4	SI, SD	Hit Invalidate	If the cache block contains the specified address, mark the cache block invalid and also invalidate all matching blocks, if present, in the primary caches (the <i>Pldx</i> field of the secondary tag is used to determine the locations in the primaries to search). The <i>CH</i> bit in the <i>Status</i> register is set or cleared to indicate a hit or miss.
5	D	Hit Writeback Invalidate	If the cache block contains the specified address, write the data back if it is dirty, and mark the cache block invalid. When a secondary cache is present, and the <i>CE</i> bit of the <i>Status</i> register is set, the contents of the <i>ECC</i> register is XOR'd into the computed check bits during the write to the secondary cache for the addressed doubleword.

## Cache (continued)

## **CACHE**

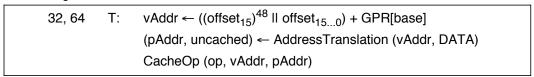

Code	Caches	Name	Operation
5	SD	Hit Writeback Invalidate	If the cache block contains the specified address, write back the data (if dirty), and mark the secondary cache block and all matching blocks in both primary caches invalid. As usual with secondary writebacks, modified data in the primary data cache (matching block with the <i>W</i> bit set) is used during the writeback. The <i>Pldx</i> field of the secondary tag is used to determine the locations in the primaries to check for matching primary blocks. The <i>CH</i> bit in the <i>Status</i> register is set or cleared to indicate a hit or miss.
5	I	Fill	Fill the primary instruction cache block from secondary cache or memory. If the $CE$ bit of the Status register is set, the content of the $ECC$ register is used instead of the computed parity bits for addressed doubleword when written to the instruction cache. For the R4000PC, the cache is filled from memory. For the R4000SC and R4000MC, the cache is filled from the secondary cache whether or not the secondary cache block is valid or contains the specified address.
6	D	Hit Writeback	If the cache block contains the specified address, and the $W$ bit is set, write back the data. The $W$ bit is not cleared; a subsequent miss to the block will write it back again. This second writeback is redundant, but not incorrect. When a secondary cache is present, and the $CE$ bit of the $Status$ register is set, the content of the $ECC$ register is XOR'd into the computed check bits during the write to the secondary cache for the addressed doubleword. Note: The $W$ bit is not cleared during this operation due to an artifact of the implementation; the $W$ bit is implemented as part of the data side of the cache array so that it can be written during a data write.
6	SD	Hit Writeback	If the cache block contains the specified address, and the cache state is Dirty Exclusive or Dirty Shared, data is written back to memory. The cache state is unchanged; a subsequent miss to the block causes it to be written back again. This second writeback is redundant, but not incorrect. The <i>CH</i> bit in the <i>Status</i> register is set or cleared to indicate a hit or miss. The writeback looks in the primary data cache for modified data, but does not invalidate or clear the Writeback bit in the primary data cache. Note: The state of the secondary block is not changed to clean during this operation because the <i>W</i> bit of matching sub-blocks cannot be cleared to put the primary block in a clean state.
6	I	Hit Writeback	If the cache block contains the specified address, data is written back unconditionally. When a secondary cache is present, and the <i>CE</i> bit of the <i>Status</i> register is set, the contents of the <i>ECC</i> register is XOR'd into the computed check bits during the write to the secondary cache for the addressed doubleword.

## Cache (continued)

## **CACHE**

Code	Caches	Name	Operation
7	SI,SD	Hit Set Virtual	This operation is used to change the virtual index of secondary cache contents, avoiding unnecessary memory operations. If the cache block contains the specified address, invalidate matching blocks in the primary caches at the index formed by concatenating <i>Pldx</i> in the secondary cache tag (not the virtual address of the operation) and vAddr <sub>114</sub> , and then set the virtual index field of the secondary cache tag from the specified virtual address. Modified data in the primary data cache is not preserved by the operation and should be explicitly written back before this operation. The <i>CH</i> bit in the <i>Status</i> register is set or cleared to indicate a hit or miss.

#### Operation:

#### **Exceptions:**

Coprocessor unusable exception

**CFCz** 

## Move Control From Coprocessor

**CFCz**

### **DADD**

#### **Doubleword Add**

## **DADD**

31 26	25 21	20 16	15 11	10 6	5 0
SPECIAL	rs	rt	rd	0	DADD
000000	10		""	00000	101100
6	5	5	5	5	6

#### **Format:**

DADD rd, rs, rt

#### **Description:**

The contents of general register *rs* and the contents of general register *rt* are added to form the result. The result is placed into general register *rd*.

An overflow exception occurs if the carries out of bits 62 and 63 differ (2's complement overflow). The destination register rd is not modified when an integer overflow exception occurs.

This operation is only defined for the R4000 operating in 64-bit mode. Execution of this instruction in 32-bit mode causes a reserved instruction exception.

#### **Operation:**

64 T:  $GPR[rd] \leftarrow GPR[rs] + GPR[rt]$ 

#### **Exceptions:**

Integer overflow exception

## **DADDI**

#### **Doubleword Add Immediate**

## **DADDI**

31 26	25 21	20 16	15 0	)
DADDI 0 1 1 0 0 0	rs	rt	immediate	
6	5	5	16	-

#### **Format:**

DADDI rt, rs, immediate

#### **Description:**

The 16-bit *immediate* is sign-extended and added to the contents of general register *rs* to form the result. The result is placed into general register *rt*.

An overflow exception occurs if carries out of bits 62 and 63 differ (2's complement overflow). The destination register rt is not modified when an integer overflow exception occurs.

This operation is only defined for the R4000 operating in 64-bit mode. Execution of this instruction in 32-bit mode causes a reserved instruction exception.

#### Operation:

64 T: GPR [rt] 
$$\leftarrow$$
 GPR[rs] + (immediate<sub>15</sub>)<sup>48</sup> | | immediate<sub>15...0</sub>

#### **Exceptions:**

Integer overflow exception Reserved instruction exception (R4000 in 32-bit mode)

## **DADDIU**

#### Doubleword Add Immediate Unsigned

## **DADDIU**

31 26	25	21 20	16 15	0
DADDIU 0 1 1 0 0 1	rs	rt		immediate
6	5	5		16

#### **Format:**

DADDIU rt, rs, immediate

#### **Description:**

The 16-bit *immediate* is sign-extended and added to the contents of general register rs to form the result. The result is placed into general register rt. No integer overflow exception occurs under any circumstances.

The only difference between this instruction and the DADDI instruction is that DADDIU never causes an overflow exception.

This operation is only defined for the R4000 operating in 64-bit mode. Execution of this instruction in 32-bit mode causes a reserved instruction exception.

#### Operation:

64 T: GPR [rt] 
$$\leftarrow$$
 GPR[rs] + (immediate<sub>15</sub>)<sup>48</sup> II immediate<sub>15...0</sub>

#### **Exceptions:**

$$s \leftarrow 1 \parallel sa$$

$$GPR[rd] \leftarrow 0^{s} \parallel GPR[rt]_{63...s}$$

#### **Exceptions:**

Reserved instruction exception (R4000 in 32-bit mode)

### **DSUB**

#### **Doubleword Subtract**

## **DSUB**

31 26	25 21	20 16	15 11	10 6	5 0	
SPECIAL 0 0 0 0 0 0	rs	rt	rd	0 0 0 0 0	DSUB 101110	
6	5	5	5	5	6	

#### Format:

DSUB rd, rs, rt

#### **Description:**

The contents of general register rt are subtracted from the contents of general register rs to form a result. The result is placed into general register rd.

The only difference between this instruction and the DSUBU instruction is that DSUBU never traps on overflow.

An integer overflow exception takes place if the carries out of bits 62 and 63 differ (2's complement overflow). The destination register rd is not modified when an integer overflow exception occurs.

This operation is only defined for the R4000 operating in 64-bit mode. Execution of this instruction in 32-bit mode causes a reserved instruction exception.

#### Operation:

64 T:  $GPR[rd] \leftarrow GPR[rs] - GPR[rt]$ 

#### **Exceptions:**

Integer overflow exception Reserved instruction exception (R4000 in 32-bit mode)

### **DSUBU** Doubleword Subtract Unsigned

# **DSUBU**

SPECIAL 0 0 0 0 0 0	rs	rt	rd	0 0 0 0 0	DSUBU 1 0 1 1 1 1
6	5	5	5	5	6

#### **Format:**

DSUBU rd, rs, rt

#### **Description:**

The contents of general register *rt* are subtracted from the contents of general register *rs* to form a result. The result is placed into general register rd.

The only difference between this instruction and the DSUB instruction is that DSUBU never traps on overflow. No integer overflow exception occurs under any circumstances.

This operation is only defined for the R4000 operating in 64-bit mode. Execution of this instruction in 32-bit mode causes a reserved instruction exception.

#### **Operation:**

64 T:  $GPR[rd] \leftarrow GPR[rs] - GPR[rt]$ 

#### **Exceptions:**

Reserved instruction exception (R4000 in 32-bit mode)

### **ERET**

#### **Exception Return**

## **ERET**

31 26	25 2	24	6	5	0
COP0 0 1 0 0 0 0	CO 1	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0		ERE 0 1 1 0	
6	1	19		6	

#### **Format:**

**ERET** 

#### **Description:**

ERET is the R4000 instruction for returning from an interrupt, exception, or error trap. Unlike a branch or jump instruction, ERET does not execute the next instruction.

ERET must not itself be placed in a branch delay slot.

If the processor is servicing an error trap ( $SR_2 = 1$ ), then load the PC from the *ErrorEPC* and clear the *ERL* bit of the *Status* register ( $SR_2$ ). Otherwise ( $SR_2 = 0$ ), load the PC from the *EPC*, and clear the *EXL* bit of the *Status* register ( $SR_1$ ).

An ERET executed between a LL and SC also causes the SC to fail.

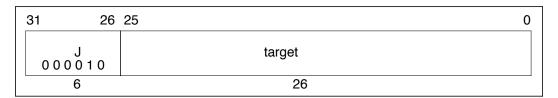

#### **Operation:**

```
32, 64 T: if SR_2 = 1 then PC \leftarrow ErrorEPC SR \leftarrow SR_{31...3} \parallel 0 \parallel SR_{1...0} else PC \leftarrow EPC SR \leftarrow SR_{31...2} \parallel 0 \parallel SR_0 endif LLbit \leftarrow 0
```

#### **Exceptions:**

Coprocessor unusable exception

J Jump

#### **Format:**

J target

#### **Description:**

The 26-bit target address is shifted left two bits and combined with the high-order bits of the address of the delay slot. The program unconditionally jumps to this calculated address with a delay of one instruction.

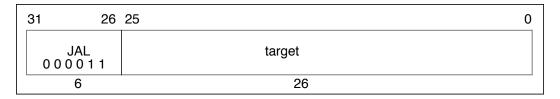

#### Operation:

#### **Exceptions:**

# **JAL**

### **Jump And Link**

**JAL** 

#### Format:

JAL target

#### **Description:**

The 26-bit target address is shifted left two bits and combined with the high-order bits of the address of the delay slot. The program unconditionally jumps to this calculated address with a delay of one instruction. The address of the instruction after the delay slot is placed in the link register, *r*31.

#### Operation:

32 T: temp  $\leftarrow$  target GPR[31]  $\leftarrow$  PC + 8

T+1: PC  $\leftarrow$  PC <sub>31...28</sub> II temp II  $0^2$ 

64 T: temp ← target

### LDL

#### **Load Doubleword Left**

31 26	25 21	20 16	15	0
LDL 011010	base	rt	offset	
6	5	5	16	

#### Format:

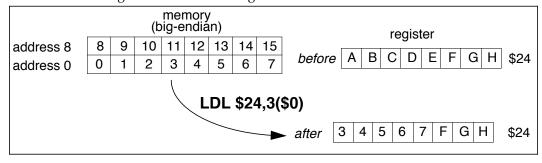

LDL rt, offset(base)

#### **Description:**

This instruction can be used in combination with the LDR instruction to load a register with eight consecutive bytes from memory, when the bytes cross a doubleword boundary. LDL loads the left portion of the register with the appropriate part of the high-order doubleword; LDR loads the right portion of the register with the appropriate part of the low-order doubleword.

The LDL instruction adds its sign-extended 16-bit *offset* to the contents of general register *base* to form a virtual address which can specify an arbitrary byte. It reads bytes only from the doubleword in memory which contains the specified starting byte. From one to eight bytes will be loaded, depending on the starting byte specified.

Conceptually, it starts at the specified byte in memory and loads that byte into the high-order (left-most) byte of the register; then it loads bytes from memory into the register until it reaches the low-order byte of the doubleword in memory. The least-significant (right-most) byte(s) of the register will not be changed.

### LDL

# Load Doubleword Left (continued)

The contents of general register rt are internally bypassed within the processor so that no NOP is needed between an immediately preceding load instruction which specifies register rt and a following LDL (or LDR) instruction which also specifies register rt.

No address exceptions due to alignment are possible.

This operation is only defined for the R4000 operating in 64-bit mode. Execution of this instruction in 32-bit mode causes a reserved instruction exception.

#### Operation:

```
64 T: vAddr ← ((offset<sub>15</sub>)<sup>48</sup> II offset<sub>15...0</sub>) + GPR[base]
(pAddr, uncached) ← AddressTranslation (vAddr, DATA)
pAddr ← pAddr<sub>PSIZE-1...3</sub> II (pAddr<sub>2...0</sub> xor ReverseEndian<sup>3</sup>)
if BigEndianMem = 0 then
pAddr ← pAddr<sub>PSIZE-1...3</sub> II 0<sup>3</sup>

#### **Load Doubleword Right**

31 26	25 21	20 16	15 0
LDR 011011	base	rt	offset
6	5	5	16

#### Format:

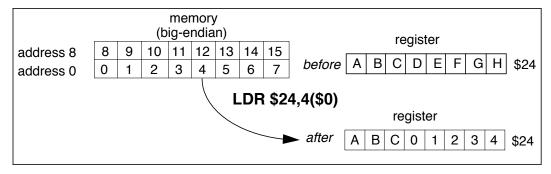

LDR rt, offset(base)

#### **Description:**

This instruction can be used in combination with the LDL instruction to load a register with eight consecutive bytes from memory, when the bytes cross a doubleword boundary. LDR loads the right portion of the register with the appropriate part of the low-order doubleword; LDL loads the left portion of the register with the appropriate part of the high-order doubleword.

The LDR instruction adds its sign-extended 16-bit *offset* to the contents of general register *base* to form a virtual address which can specify an arbitrary byte. It reads bytes only from the doubleword in memory which contains the specified starting byte. From one to eight bytes will be loaded, depending on the starting byte specified.

Conceptually, it starts at the specified byte in memory and loads that byte into the low-order (right-most) byte of the register; then it loads bytes from memory into the register until it reaches the high-order byte of the doubleword in memory. The most significant (left-most) byte(s) of the register will not be changed.

## **LDR**

# Load Doubleword Right (continued)

The contents of general register rt are internally bypassed within the processor so that no NOP is needed between an immediately preceding load instruction which specifies register rt and a following LDR (or LDL) instruction which also specifies register rt.

No address exceptions due to alignment are possible.

This operation is only defined for the R4000 operating in 64-bit mode. Execution of this instruction in 32-bit mode causes a reserved instruction exception.

#### Operation:

```
64 T: vAddr ← ((offset<sub>15</sub>)<sup>48</sup> II offset<sub>15...0</sub>) + GPR[base]
(pAddr, uncached) ← AddressTranslation (vAddr, DATA)

# Load Linked

31 :	26 2	25 21	20 16	15 (	0
LL 11000	0	base	rt	offset	
6	·	5	5	16	_

#### Format:

LL rt, offset(base)

#### **Description:**

The 16-bit *offset* is sign-extended and added to the contents of general register *base* to form a virtual address. The contents of the word at the memory location specified by the effective address are loaded into general register *rt*. In 64-bit mode, the loaded word is sign-extended.

The processor begins checking the accessed word for modification by other processor and devices.

Load Linked and Store Conditional can be used to atomically update memory locations as shown:

This atomically increments the word addressed by T0. Changing the ADD to an OR changes this to an atomic bit set. This instruction is available in User mode, and it is not necessary for CP0 to be enabled.

The operation of LL is undefined if the addressed location is uncached and, for synchronization between multiple processors, the operation of LL is undefined if the addressed location is noncoherent. A cache miss that occurs between LL and SC may cause SC to fail, so no load or store operation should occur between LL and SC, otherwise the SC may never be successful. Exceptions also cause SC to fail, so persistent exceptions must be avoided. If either of the two least-significant bits of the effective address are non-zero, an address error exception takes place.

### $\mathsf{L}\mathsf{L}$

# Load Linked (continued)

### **LWL**

#### **Load Word Left**

### LWL

31 26	25 21	20 16	15	0
LWL 100010	base	rt	offset	
6	5	5	16	

#### **Format:**

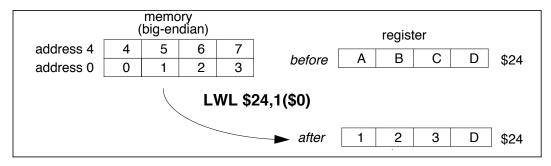

LWL rt, offset(base)

#### **Description:**

This instruction can be used in combination with the LWR instruction to load a register with four consecutive bytes from memory, when the bytes cross a word boundary. LWL loads the left portion of the register with the appropriate part of the high-order word; LWR loads the right portion of the register with the appropriate part of the low-order word.

The LWL instruction adds its sign-extended 16-bit *offset* to the contents of general register *base* to form a virtual address which can specify an arbitrary byte. It reads bytes only from the word in memory which contains the specified starting byte. From one to four bytes will be loaded, depending on the starting byte specified. In 64-bit mode, the loaded word is sign-extended.

Conceptually, it starts at the specified byte in memory and loads that byte into the high-order (left-most) byte of the register; then it loads bytes from memory into the register until it reaches the low-order byte of the word in memory. The least-significant (right-most) byte(s) of the register will not be changed.

## **LWL**

# Load Word Left (continued)

**LWL** 

The contents of general register rt are internally bypassed within the processor so that no NOP is needed between an immediately preceding load instruction which specifies register rt and a following LWL (or LWR) instruction which also specifies register rt. No address exceptions due to alignment are possible.

#### **Operation:**

```
vAddr \leftarrow ((offset_{15})^{16} | I | offset_{15...0}) + GPR[base]
32
        T:
               (pAddr, uncached) ← AddressTranslation (vAddr, DATA)
               pAddr \leftarrow pAddr_{PSIZE-1...3} II (pAddr_{2...0} xor ReverseEndian^3)
                if BigEndianMem = 0 then
                      pAddr \leftarrow pAddr_{PSIZE-1...2} \parallel 0^2
               endif

### **LWR**

#### **Load Word Right**

## **LWR**

31 26	25 21	20 16	15 0	
LWR 100110	base	rt	offset	
6	5	5	16	

#### **Format:**

LWR rt, offset(base)

#### **Description:**

This instruction can be used in combination with the LWL instruction to load a register with four consecutive bytes from memory, when the bytes cross a word boundary. LWR loads the right portion of the register with the appropriate part of the low-order word; LWL loads the left portion of the register with the appropriate part of the high-order word.

The LWR instruction adds its sign-extended 16-bit *offset* to the contents of general register *base* to form a virtual address which can specify an arbitrary byte. It reads bytes only from the word in memory which contains the specified starting byte. From one to four bytes will be loaded, depending on the starting byte specified. In 64-bit mode, if bit 31 of the destination register is loaded, then the loaded word is sign-extended.

Conceptually, it starts at the specified byte in memory and loads that byte into the low-order (right-most) byte of the register; then it loads bytes from memory into the register until it reaches the high-order byte of the word in memory. The most significant (left-most) byte(s) of the register will not be changed.

### **LWR**

# Load Word Right (continued)

# **LWR**

The contents of general register rt are internally bypassed within the processor so that no NOP is needed between an immediately preceding load instruction which specifies register rt and a following LWR (or LWL) instruction which also specifies register rt. No address exceptions due to alignment are possible.

#### Operation:

```
vAddr \leftarrow ((offset_{15})^{16} | I | offset_{15}) + GPR[base]
32
        T:

## **LWU**

#### **Load Word Unsigned**

# **LWU**

3	1 26	25 21	20 16	15 0	)
	LWU 100111	base	rt	offset	
	6	5	5	16	

#### **Format:**

LWU rt, offset(base)

#### **Description:**

The 16-bit *offset* is sign-extended and added to the contents of general register *base* to form a virtual address. The contents of the word at the memory location specified by the effective address are loaded into general register *rt*. The loaded word is zero-extended.

If either of the two least-significant bits of the effective address is non-zero, an address error exception occurs.

This operation is only defined for the R4000 operating in 64-bit mode. Execution of this instruction in 32-bit mode causes a reserved instruction exception.

#### **Operation:**

#### **Exceptions:**

TLB refill exception
TLB invalid exception
Bus error exception
Address error exception
Reserved instruction exception (R4000 in 32-bit mode)

#### **Store Conditional**

SC

31	26	25 21	20 16	15 0
1 1	SC 1000	base	rt	offset
	6	5	5	16

#### **Format:**

SC rt, offset(base)

#### **Description:**

The 16-bit offset is sign-extended and added to the contents of general register *base* to form a virtual address. The contents of general register *rt* are conditionally stored at the memory location specified by the effective address.

If any other processor or device has modified the physical address since the time of the previous Load Linked instruction, or if an ERET instruction occurs between the Load Linked instruction and this store instruction, the store fails and is inhibited from taking place.

The success or failure of the store operation (as defined above) is indicated by the contents of general register rt after execution of the instruction. A successful store sets the contents of general register rt to 1; an unsuccessful store sets it to 0.

The operation of Store Conditional is undefined when the address is different from the address used in the last Load Linked.

This instruction is available in User mode; it is not necessary for CP0 to be enabled.

If either of the two least-significant bits of the effective address is non-zero, an address error exception takes place.

If this instruction should both fail and take an exception, the exception takes precedence.

## SC

### SDL

#### **Store Doubleword Left**

31 26	25 21	20 16	15 (	)
SDL 101100	base	rt	offset	
6	5	5	16	_

#### **Format:**

SDL rt, offset(base)

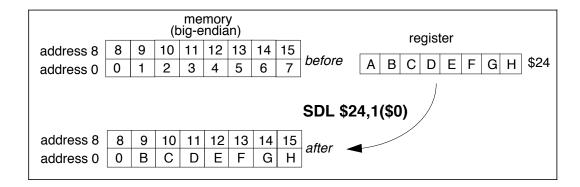

#### **Description:**

This instruction can be used with the SDR instruction to store the contents of a register into eight consecutive bytes of memory, when the bytes cross a doubleword boundary. SDL stores the left portion of the register into the appropriate part of the high-order doubleword of memory; SDR stores the right portion of the register into the appropriate part of the low-order doubleword.

The SDL instruction adds its sign-extended 16-bit *offset* to the contents of general register *base* to form a virtual address which may specify an arbitrary byte. It alters only the word in memory which contains that byte. From one to four bytes will be stored, depending on the starting byte specified.

Conceptually, it starts at the most-significant byte of the register and copies it to the specified byte in memory; then it copies bytes from register to memory until it reaches the low-order byte of the word in memory.

No address exceptions due to alignment are possible.

### **SDL**

# Store Doubleword Left (continued)

### SH

#### **Store Halfword**

_		
_		
•		
$\mathbf{-}$		

31 26	25 21	20 16	15 0	)
SH 101001	base	rt	offset	
6	5	5	16	-

#### Format:

SH rt, offset(base)

#### **Description:**

The 16-bit *offset* is sign-extended and added to the contents of general register *base* to form an unsigned effective address. The least-significant halfword of register *rt* is stored at the effective address. If the least-significant bit of the effective address is non-zero, an address error exception occurs.

#### Operation:

#### **Exceptions:**

TLB refill exception TLB invalid exception TLB modification exception Bus error exception Address error exception SLL

#### **Shift Left Logical**

SLL

31	26	25	21	20	16	15	11	10		6	5		0
SPECI 0 0 0 0 0		0 0 0 0	0	rt		r	d		sa		0 0	SLL 00000	
6		5		5		5			5			6	

#### **Format:**

SLL rd, rt, sa

#### **Description:**

The contents of general register *rt* are shifted left by *sa* bits, inserting zeros into the low-order bits.

The result is placed in register *rd*.

In 64-bit mode, the 32-bit result is sign extended when placed in the destination register. It is sign extended for all shift amounts, including zero; SLL with a zero shift amount truncates a 64-bit value to 32 bits and then sign extends this 32-bit value. SLL, unlike nearly all other word operations, does not require an operand to be a properly sign-extended word value to produce a valid sign-extended word result.

**NOTE:** SLL with a shift amount of zero may be treated as a NOP by some assemblers, at some optimization levels. If using SLL with a zero shift to truncate 64-bit values, check the assembler you are using.

#### Operation:

32 T: GPR[rd] 
$$\leftarrow$$

SWL rt, offset(base)

5

#### **Description:**

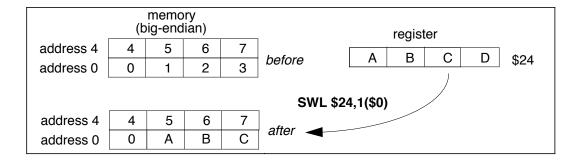

This instruction can be used with the SWR instruction to store the contents of a register into four consecutive bytes of memory, when the bytes cross a word boundary. SWL stores the left portion of the register into the appropriate part of the high-order word of memory; SWR stores the right portion of the register into the appropriate part of the low-order word.

16

The SWL instruction adds its sign-extended 16-bit *offset* to the contents of general register *base* to form a virtual address which may specify an arbitrary byte. It alters only the word in memory which contains that byte. From one to four bytes will be stored, depending on the starting byte specified.

Conceptually, it starts at the most-significant byte of the register and copies it to the specified byte in memory; then it copies bytes from register to memory until it reaches the low-order byte of the word in memory.

No address exceptions due to alignment are possible.

### **SWR**

### **Store Word Right**

# **SWR**

#### **Format:**

SWR rt, offset(base)

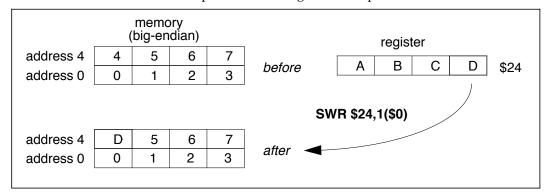

#### **Description:**

This instruction can be used with the SWL instruction to store the contents of a register into four consecutive bytes of memory, when the bytes cross a boundary between two words. SWR stores the right portion of the register into the appropriate part of the low-order word; SWL stores the left portion of the register into the appropriate part of the low-order word of memory.

The SWR instruction adds its sign-extended 16-bit *offset* to the contents of general register *base* to form a virtual address which may specify an arbitrary byte. It alters only the word in memory which contains that byte. From one to four bytes will be stored, depending on the starting byte specified.

Conceptually, it starts at the least-significant (rightmost) byte of the register and copies it to the specified byte in memory; then copies bytes from register to memory until it reaches the high-order byte of the word in memory.

No address exceptions due to alignment are possible.

### **Synchronize**

## SYNC

31 26	25	6	5	0
SPECIAL 000000	0000 0000 0000 0000 0000		SYN 0 0 1	
6	20		6	

#### **Format:**

**SYNC** 

#### **Description:**

The SYNC instruction ensures that any loads and stores fetched *prior to* the present instruction are completed before any loads or stores *after* this instruction are allowed to start. Use of the SYNC instruction to serialize certain memory references may be required in a multiprocessor environment for proper synchronization. For example:

Pr	Processor A			
SW	R1, DATA	1:	LW	R2, FLAG
LI	R2, 1		BEQ	R2, R0, 1B
SYNC			NOP	
SW	R2, FLAG		SYNC	
			LW	R1, DATA

The SYNC in processor A prevents DATA being written after FLAG, which could cause processor B to read stale data. The SYNC in processor B prevents DATA from being read before FLAG, which could likewise result in reading stale data. For processors which only execute loads and stores in order, with respect to shared memory, this instruction is a NOP.

LL and SC instructions implicitly perform a SYNC.

This instruction is allowed in User mode.

Figure A-2 (cont.) R4000 Opcode Bit Encoding

### Key:

- \* Operation codes marked with an asterisk cause reserved instruction exceptions in all current implementations and are reserved for future versions of the architecture.
- γ Operation codes marked with a gamma cause a reserved instruction exception. They are reserved for future versions of the architecture.
- $\delta$  Operation codes marked with a delta are valid only for R4000 processors with CP0 enabled, and cause a reserved instruction exception on other processors.
- φ Operation codes marked with a phi are invalid but do not cause reserved instruction exceptions in R4000 implementations.
- ξ Operation codes marked with a xi cause a reserved instruction exception on R4000 processors.
- χ Operation codes marked with a chi are valid only on R4000.
- ε Operation codes marked with epsilon are valid when the processor is operating either in the Kernel mode or in the 64-bit non-Kernel (User or Supervisor) mode. These instructions cause a reserved instruction exception if 64-bit operation is not enabled in User or Supervisor mode.

### FPU Instruction Set Details

B

This appendix provides a detailed description of each floating-point unit (FPU) instruction (refer to Appendix A for a detailed description of the CPU instructions). The instructions are listed alphabetically, and any exceptions that may occur due to the execution of each instruction are listed after the description of each instruction. Descriptions of the immediate causes and the manner of handling exceptions are omitted from the instruction descriptions in this appendix (refer to Chapter 7 for detailed descriptions of floating-point exceptions and handling).

Figure B-3 at the end of this appendix lists the entire bit encoding for the constant fields of the floating-point instruction set; the bit encoding for each instruction is included with that individual instruction.

### **B.1** Instruction Formats

There are three basic instruction format types:

- I-Type, or Immediate instructions, which include load and store operations
- M-Type, or Move instructions
- R-Type, or Register instructions, which include the twoand three-register floating-point operations.

The instruction description subsections that follow show how these three basic instruction formats are used by:

- Load and store instructions
- Move instructions
- Floating-Point computational instructions
- Floating-Point branch instructions

Floating-point instructions are mapped onto the MIPS coprocessor instructions, defining coprocessor unit number one (CP1) as the floating-point unit.

Each operation is valid only for certain formats. Implementations may support some of these formats and operations through emulation, but they only need to support combinations that are valid (marked V in Table B-1). Combinations marked R in Table B-1 are not currently specified by this architecture, and cause an unimplemented operation trap. They will be available for future extensions to the architecture.

Table B-1 Valid FPU Instruction Formats

Omanation	Source Format							
Operation	Single	Double	Word	Longword				
ADD	V	V	R	R				
SUB	V	V	R	R				
MUL	V	V	R	R				
DIV	V	V	R	R				
SQRT	V	V	R	R

CVT.S		V	V	V				
CVT.D	V		V	V				
CVT.W	V	V						
CVT.L	V	V						
С	V	V	R	R				

The coprocessor branch on condition true/false instructions can be used to logically negate any predicate. Thus, the 32 possible conditions require only 16 distinct comparisons, as shown in Table B-2 below.

Table B-2 Logical Negation of Predicates by Condition True/False

Condition					Invalid		
Mnemonic True False		Code	Greater Than	Less Than	Equal	Unordered	Operation Exception If Unordered

NGT	GT	15	F	Т	Т	Т	Yes

### Floating-Point Loads, Stores, and Moves

All movement of data between the floating-point coprocessor and memory is accomplished by coprocessor load and store operations, which reference the floating-point coprocessor *General Purpose* registers. These operations are unformatted; no format conversions are performed and, therefore, no floating-point exceptions can occur due to these operations.

Data may also be directly moved between the floating-point coprocessor and the processor by *move to coprocessor* and *move from coprocessor* instructions. Like the floating-point load and store operations, move to/from operations perform no format conversions and never cause floating-point exceptions.

An additional pair of coprocessor registers are available, called *Floating-Point Control* registers for which the only data movement operations supported are moves to and from processor *General Purpose* registers.

### **Floating-Point Operations**

The floating-point unit operation set includes:

- floating-point add
- floating-point subtract
- floating-point multiply
- floating-point divide
- floating-point square root
- convert between fixed-point and floating-point formats
- convert between floating-point formats
- floating-point compare

These operations satisfy the requirements of IEEE Standard 754 requirements for accuracy. Specifically, these operations obtain a result which is identical to an infinite-precision result rounded to the specified format, using the current rounding mode.

Instructions must specify the format of their operands. Except for conversion functions, mixed-format operations are not provided.

### **B.2 Instruction Notation Conventions**

In this appendix, all variable subfields in an instruction format (such as *fs*, *ft*, *immediate*, and so on) are shown in lower-case. The instruction name (such as ADD, SUB, and so on) is shown in upper-case.

For the sake of clarity, we sometimes use an alias for a variable subfield in the formats of specific instructions. For example, we use rs = base in the format for load and store instructions. Such an alias is always lower case, since it refers to a variable subfield.

In some instructions, the instruction subfields op and function can have constant 6-bit values. When reference is made to these instructions, upper-case mnemonics are used. For instance, in the floating-point ADD instruction we use op = COP1 and function = ADD. In other cases, a single field has both fixed and variable subfields, so the name contains both upper and lower case characters. Bit encodings for mnemonics are shown in Figure B-3 at the end of this appendix, and are also included with each individual instruction.

In the instruction description examples that follow, the *Operation* section describes the operation performed by each instruction using a high-level language notation.

### **Instruction Notation Examples**

The following examples illustrate the application of some of the instruction notation conventions:

### Example #1:

GPR[rt] ← immediate II 0<sup>16</sup>

Sixteen zero bits are concatenated with an immediate value (typically 16 bits), and the 32-bit string (with the lower 16 bits set to zero) is assigned to General Purpose Register *rt*.

#### Example #2:

(immediate<sub>15</sub>)<sup>16</sup> II immediate<sub>15...0</sub>

Bit 15 (the sign bit) of an immediate value is extended for 16 bit positions, and the result is concatenated with bits 15 through 0 of the immediate value to form a 32-bit sign extended value.

### **B.3** Load and Store Instructions

In the R4000 implementation, the instruction immediately following a load may use the contents of the register being loaded. In such cases, the hardware *interlocks*, requiring additional real cycles, so scheduling load delay slots is still desirable, although not required for functional code.

The behavior of the load store instructions is dependent on the width of the *FGR*s.

- When the *FR* bit in the *Status* register equals zero, the *Floating-Point General* registers (*FGRs*) are 32-bits wide.
- When the FR bit in the Status register equals one, the Floating-Point General registers (FGRs) are 64-bits wide.

In the load and store operation descriptions, the functions listed in Table B-3 are used to summarize the handling of virtual addresses and physical memory.

Table B-3 Load and Store Common Functions

Function	Meaning
AddressTranslation	Uses the TLB to find the physical address given the virtual address. The function fails and an exception is taken if the required translation is not present in the TLB.
LoadMemory	Uses the cache and main memory to find the contents of the word containing the specified physical address. The low-order two bits of the address and the <i>Access Type</i> field indicates which of each of the four bytes within the data word need to be returned. If the cache is enabled for this access, the entire word is returned and loaded into the cache.
StoreMemory	Uses the cache, write buffer, and main memory to store the word or part of word specified as data in the word containing the specified physical address. The low-order two bits of the address and the <i>Access Type</i> field indicates which of each of the four bytes within the data word should be stored.

Figure B-1 shows the I-Type instruction format used by load and store operations.

### I-Type (Immediate)

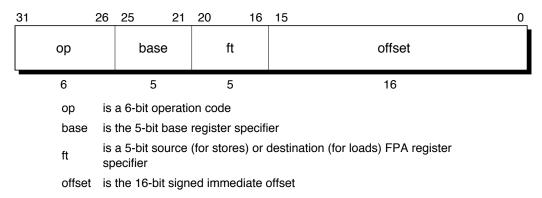

Figure B-1 Load and Store Instruction Format

All coprocessor loads and stores reference aligned data items. Thus, for word loads and stores, the access type field is always WORD, and the low-order two bits of the address must always be zero.

For doubleword loads and stores, the access type field is always DOUBLEWORD, and the low-order three bits of the address must always be zero.

Regardless of byte-numbering order (endianness), the address specifies that byte which has the smallest byte-address in the addressed field. For a big-endian machine, this is the leftmost byte; for a little-endian machine, this is the rightmost byte.

### **B.4** Computational Instructions

Computational instructions include all of the arithmetic floating-point operations performed by the FPU.

Figure B-2 shows the R-Type instruction format used for computational operations.

### R-Type (Register)

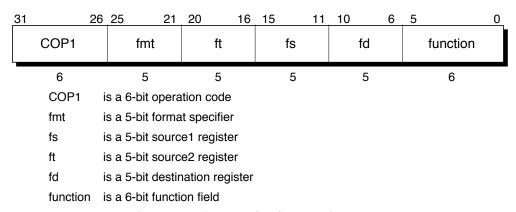

Figure B-2 Computational Instruction Format

The *function* field indicates the floating-point operation to be performed.

Each floating-point instruction can be applied to a number of operand *formats*. The operand format for an instruction is specified by the 5-bit *format* field; decoding for this field is shown in Table B-4.

Code	Mnemonic	Size	Format			
16	S	single	Binary floating-point

33	CVT.D	Convert to double floating-point
34	_	Reserved
35	_	Reserved
36	CVT.W	Convert to 32-bit binary fixed-point
37	CVT.L	Convert to 64-bit (long) binary fixed-point
38–47	_	Reserved
48-63	С	Floating-point compare

In the following pages, the notation *FGR* refers to the 32 *General Purpose* registers *FGR0* through *FGR31* of the FPU, and *FPR* refers to the floating-point registers of the FPU.

- When the *FR* bit in the *Status* register (SR(26)) equals zero, only the even floating-point registers are valid and the 32 *General Purpose* registers of the FPU are 32-bits wide.
- When the *FR* bit in the *Status* register (SR(26)) equals one, both odd and even floating-point registers may be used and the 32 *General Purpose* registers of the FPU are 64-bits wide.

The following routines are used in the description of the floating-point operations to retrieve the value of an FPR or to change the value of an FGR:

```
value ← ValueFPR(fpr,fmt)
 if SR_{26} = 1 then /* 64-bit wide FGRs */
      case fmt of
          S, W:
               value \leftarrow FGR[fpr]<sub>31...0</sub>
               return
          D. L:
               value ← FGR[fpr]
               return
      endcase
 elseif fpr<sub>0</sub> = 0 then /* valid specifier, 32-bit wide FGRs */
      case fmt of
          S, W:
              value ← FGR[fpr]
               return
          D, L:
               value ← FGR[fpr+1] II FGR[fpr]
               return
      endcase
 else /* undefined result for odd 32-bit reg #s */
      value ← undefined
 endif
```

```
StoreFPR(fpr, fmt, value)
 if SR_{26} = 1 then /* 64-bit wide FGRs */
     case fmt of
          S, W:
              FGR[fpr] ← undefined<sup>32</sup> II value
              return
          D, L:
              FGR[fpr] ← value
              return
     endcase
 elseif fpr_0 = 0 then /* valid specifier, 32-bit wide FGRs */
     case fmt of
          S, W:
              FGR[fpr+1] \leftarrow undefined
              FGR[fpr] ← value
              return
          D, L:
              FGR[fpr+1] \leftarrow value_{63...32}
              FGR[fpr] \leftarrow value_{31...0}
              return
      endcase
 else /* undefined result for odd 32-bit reg #s */
      undefined_result
 endif
```

6		5			5		5		5	6	

### **Format:**

ABS.fmt fd, fs

### **Description:**

The contents of the FPU register specified by *f*s are interpreted in the specified format and the arithmetic absolute value is taken. The result is placed in the floating-point register specified by *fd*.

The absolute value operation is arithmetic; a NaN operand signals invalid operation.

This instruction is valid only for single- and double-precision floating-point formats. The operation is not defined if bit 0 of any register specification is set and the *FR* bit in the *Status* register equals zero, since the register numbers specify an even-odd pair of adjacent coprocessor general registers. When the *FR* bit in the *Status* register equals one, both even and odd register numbers are valid.

### **Operation:**

T: StoreFPR(fd, fmt, AbsoluteValue(ValueFPR(fs, fmt)))

### **Exceptions:**

Coprocessor unusable exception Coprocessor exception trap

### **Coprocessor Exceptions:**

Unimplemented operation exception Invalid operation exception

## ADD.fmt

### Floating-Point Add

31	26	25 21	20 16	3 15	11 10	6 5 0
COP1 0 1 0 0 0	1	fmt	ft	fs	fd	ADD 0 0 0 0 0
6		5	5	5	5	6

#### Format:

ADD.fmt fd, fs, ft

### **Description:**

The contents of the FPU registers specified by fs and ft are interpreted in the specified format and arithmetically added. The result is rounded as if calculated to infinite precision and then rounded to the specified format (fmt), according to the current rounding mode. The result is placed in the floating-point register (FPR) specified by fd.

This instruction is valid only for single- and double-precision floating-point formats. The operation is not defined if bit 0 of any register specification is set and the FR bit in the Status register equals zero, since the register numbers specify an even-odd pair of adjacent coprocessor general registers. When the FR bit in the Status register equals one, both even and odd register numbers are valid.

### **Operation:**

T: StoreFPR (fd, fmt, ValueFPR(fs, fmt) + ValueFPR(ft, fmt))

### **Exceptions:**

Coprocessor unusable exception Floating-Point exception

### **Coprocessor Exceptions:**

Unimplemented operation exception Invalid operation exception Inexact exception Overflow exception Underflow exception

```

### **Exceptions:**

## C.cond.fmt

## Floating-Point Compare

## C.cond.fmt

31 26	25 21	20 16	15 11	10 6	5 43	3 0
COP1 0 1 0 0 0 1	fmt	ft	fs	0	FC*	cond*
6	5	5	5	5	2	4

### **Format:**

C.cond.fmt fs, ft

### **Description:**

The contents of the floating-point registers specified by *fs* and *ft* are interpreted in the specified format, *fmt*, and arithmetically compared.

A result is determined based on the comparison and the conditions specified in the *cond* field. If one of the values is a Not a Number (NaN), and the high-order bit of the *cond* field is set, an invalid operation exception is taken. After a one-instruction delay, the condition is available for testing with branch on floating-point coprocessor condition instructions. There must be at least one instruction between the compare and the branch.

Comparisons are exact and can neither overflow nor underflow. Four mutually-exclusive relations are possible results: less than, equal, greater than, and unordered. The last case arises when one or both of the operands are NaN; every NaN compares unordered with everything, including itself.

Comparisons ignore the sign of zero, so +0 = -0.

This instruction is valid only for single- and double-precision floating-point formats. The operation is not defined if bit 0 of any register specification is set and the *FR* bit in the *Status* register equals zero, since the register numbers specify an even-odd pair of adjacent coprocessor general registers. When the *FR* bit in the *Status* register equals one, both even and odd register numbers are valid.

\*See "FPU Instruction Opcode Bit Encoding" at the end of Appendix B.

### C.cond.fmt

### Floating-Point Compare (continued)

## C.cond.fmt

### **Operation:**

```
T:
         if NaN(ValueFPR(fs, fmt)) or NaN(ValueFPR(ft, fmt)) then
                  less ← false
                  equal ← false
                  unordered ← true
                  if cond<sub>3</sub> then
                       signal InvalidOperationException
                  endif
         else
                  less ← ValueFPR(fs, fmt) < ValueFPR(ft, fmt)
                  equal ← ValueFPR(fs, fmt) = ValueFPR(ft, fmt)
                  unordered ← false
         endif
         condition \leftarrow (cond<sub>2</sub> and less) or (cond<sub>1</sub> and equal) or
                          (cond<sub>0</sub> and unordered)
         FCR[31]_{23} \leftarrow condition
         COC[1] \leftarrow condition
```

### **Exceptions:**

## FLOOR.L.fmt

### Floating-Point Floor to Long Fixed-Point Format

## FLOOR.L.fmt

31	26	25	21	20	16	15		11	10		6	5		0
COP1 0 1 0 0 0	1		fmt	0 (	0 0 0 0		fs			fd			FLOOR.L 0 0 1 0 1 1	
6			5		5		5	'		5			6	

### **Format:**

FLOOR.L.fmt fd, fs

### **Description:**

The contents of the floating-point register specified by fs are interpreted in the specified source format, fint, and arithmetically converted to the long fixed-point format. The result is placed in the floating-point register specified by fd.

Regardless of the setting of the current rounding mode, the conversion is rounded as if the current rounding mode is round to  $-\infty$  (3).

This instruction is valid only for conversion from single- or double-precision floating-point formats.

When the source operand is an Infinity, NaN, or the correctly rounded integer result is outside of  $-2^{63}$  to  $2^{63}$ –1, the Invalid operation exception is raised. If the Invalid operation is not enabled then no exception is taken and  $2^{63}$ –1 is returned.

### FLOOR.L.fmt

#### Floating-Point Floor to Long Fixed-Point Format (continued)

## **FLOOR.L.fmt**

#### **Operation:**

T: StoreFPR(fd, L, ConvertFmt(ValueFPR(fs, fmt), fmt, L))

#### **Exceptions:**

Coprocessor unusable exception Floating-Point exception

#### **Coprocessor Exceptions:**

# FLOOR.W.fmt Floating-Point Floor to Single Fixed-Point Format

31	26	25	21	20	16	15		11	10	(	6	5	0
COP1 0 1 0 0 0			fmt	0 0	0		fs			fd		FLOOR.W 0 0 1 1 1 1	
6			5		5		5			5		6	

#### **Format:**

FLOOR.W.fmt fd, fs

#### **Description:**

The contents of the floating-point register specified by fs are interpreted in the specified source format, fmt, and arithmetically converted to the single fixed-point format. The result is placed in the floating-point register specified by fd.

Regardless of the setting of the current rounding mode, the conversion is rounded as if the current rounding mode is round to  $-\infty$  (RM = 3).

This instruction is valid only for conversion from a single- or double-precision floating-point formats. The operation is not defined if bit 0 of any register specification is set and the FR bit in the Status register equals zero, since the register numbers specify an even-odd pair of adjacent coprocessor general registers. When the FR bit in the Status register equals one, both even and odd register numbers are valid.

When the source operand is an Infinity or NaN, or the correctly rounded integer result is outside of  $-2^{31}$  to  $2^{31}$ –1, an Invalid operation exception is raised. If Invalid operation is not enabled, then no exception is taken and  $2^{31}$ –1 is returned.

# FLOOR.W.fmt Floating-Point Floor to Single Fixed-Point Format (continued)

#### **Operation:**

T: StoreFPR(fd, W, ConvertFmt(ValueFPR(fs, fmt), fmt, W))

#### **Exceptions:**

Coprocessor unusable exception Floating-Point exception

# LDC<sub>1</sub>

# Load Doubleword to FPU (Coprocessor 1)

# LDC<sub>1</sub>

31	26	25	21	20		16	15 0	
LDC1 1 1 0 1 0	1	base	)		ft		offset	
6		5			5	•	16	

#### Format:

LDC1 ft, offset(base)

#### **Description:**

The 16-bit *offset* is sign-extended and added to the contents of general register *base* to form an unsigned effective address.

In 32-bit mode, the contents of the doubleword at the memory location specified by the effective address is loaded into registers ft and ft+1 of the floating-point coprocessor. This instruction is not valid, and is undefined, when the least significant bit of ft is non-zero.

In 64-bit mode, the contents of the doubleword at the memory location specified by the effective address are loaded into the 64-bit register *ft* of the floating point coprocessor.

The FR bit of the Status register ( $SR_{26}$ ) specifies whether all 32 registers of the R4000 are addressable. If FR equals zero, this instruction is not defined when the least significant bit of ft is non-zero. If FR equals one, ft may specify either odd or even registers.

If any of the three least-significant bits of the effective address are non-zero, an address error exception takes place.

### **TRUNC.L.fmt**

# Floating-Point Truncate to Long Fixed-Point Format

# TRUNC.L.fmt

31	26	25	21	20	16	15	1	1	10	6	5		0
COP1 010001			fmt	0 (	0		fs		fd			TRUNC.L 0 0 1 0 01	
6			5		5		5		5			6	

#### **Format:**

TRUNC.L.fmt fd, fs

#### **Description:**

The contents of the floating-point register specified by fs are interpreted in the specified source format, fint, and arithmetically converted to the long fixed-point format. The result is placed in the floating-point register specified by fd.

Regardless of the setting of the current rounding mode, the conversion is rounded as if the current rounding mode is round toward zero (1).

This instruction is valid only for conversion from single- or double-precision floating-point formats.

When the source operand is an Infinity, NaN, or the correctly rounded integer result is outside of  $-2^{63}$  to  $2^{63}$ –1, the Invalid operation exception is raised. If the Invalid operation is not enabled then no exception is taken and  $2^{63}$ –1 is returned.

### **TRUNC.L.fmt**

# Floating-Point Truncate to Long Fixed-Point Format (continued)

# **TRUNC.L.fmt**

#### **Operation:**

T: StoreFPR(fd, L, ConvertFmt(ValueFPR(fs, fmt), fmt, L))

#### **Exceptions:**

Coprocessor unusable exception Floating-Point exception

#### **Coprocessor Exceptions:**

# TRUNC.W.fmt Floating-Point TRUNC.W.fmt Truncate to Single Fixed-Point Format

Ī	31	26	25	21	20	16	15		11	10		6	5		0
	COP1 010001	1		fmt	0 (	0 0 0 0		fs			fd			TRUNC.W 0 0 1 1 0 1	
	6			5		5		5			5			6	

#### Format:

TRUNC.W.fmt fd, fs

#### **Description:**

The contents of the FPU register specified by *f*s are interpreted in the specified source format *fmt* and arithmetically converted to the single fixed-point format. The result is placed in the FPU register specified by *fd*.

Regardless of the setting of the current rounding mode, the conversion is rounded as if the current rounding mode is round toward zero (RM = 1).

This instruction is valid only for conversion from a single- or double-precision floating-point formats. The operation is not defined if bit 0 of any register specification is set and the FR bit in the Status register equals zero, since the register numbers specify an even-odd pair of adjacent coprocessor general registers. When the FR bit in the Status register equals one, both even and odd register numbers are valid.

When the source operand is an Infinity or NaN, or the correctly rounded integer result is outside of  $-2^{31}$  to  $2^{31-1}$ , an Invalid operation exception is raised. If Invalid operation is not enabled, then no exception is taken and  $-2^{31}$  is returned.

# TRUNC.W.fmt Floating-Point TRUNC.W.fmt Truncate to Single Fixed-Point Format (continued)

#### **Operation:**

T: StoreFPR(fd, W, ConvertFmt(ValueFPR(fs, fmt), fmt, W))

#### **Exceptions:**

Coprocessor unusable exception Floating-Point exception

#### **Coprocessor Exceptions:**

#### Key:

- γ Operation codes marked with a gamma cause a reserved instruction exception. They are reserved for future versions of the architecture.
- δ Operation codes marked with a delta cause unimplemented operation exceptions in all current implementations and are reserved for future versions of the architecture.
- η Operation codes marked with an eta are valid only when MIPS III instructions are enabled. Any attempt to execute these without MIPS III instructions enabled causes an unimplemented operation exception.
